

RDA012M4MS

12 Bit 1.3 GS/s Master-Slave 4:1 MUXDAC

Features

- ◆ 12 Bit Resolution
- ◆ 1.3 GS/s Sampling Rate
- ◆ 4:1 Input Multiplexer
- ◆ Master-Slave Operation for Synchronous Operation of Multiple Devices
- ◆ Differential Analog Output
- ◆ Input Code Format: Offset Binary
- ◆ Output Swing: 600 mV with 50 Ω Termination
- ◆ 3.3V NMOS-Compatible Data Inputs
- ◆ Differential ECL or Sinusoidal Clock Input
- ◆ LVDS Compatible Clock Output
- ◆ 10 Bit Static Linearity
- ◆ Reference Output/Input Pin for Accurate Full-Scale Adjustment.
- ◆ 3.3V and -5.2V Power Supply
- ◆ 77 Lead HSD or 88 Lead QFP Package

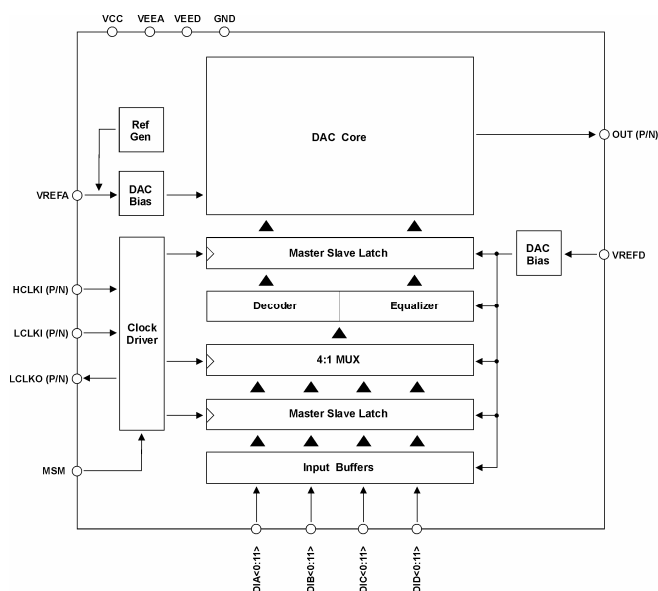

Figure 1 - Functional Block Diagram

Product Description

The RDA012M4MS is a digital-to-analog converter (DAC) with a 4:1 input multiplexer and a maximum update rate of 1.3GS/s. The RDA012M4MS features master-slave operation that simplifies synchronization when multiple devices are required, such as in an I-Q modulation scheme. The integrated DAC utilizes a segmented current source to reduce the glitch

energy and achieve high linearity performance. For best dynamic performance, the DAC outputs are internally terminated with 50Ω resistance, and outputs a nominal full-scale current of 12mA when terminated with external 50Ω resistors. For a convenient interface with most CMOS ICs, the digital data inputs are low voltage NMOS compatible.

EVRDA012M4MS-QP	RDA012M4MS-QP Evaluation Board

CAUTION
DEVICE SUSCEPTIBLE TO
DAMAGE BY ELECTROSTATIC
DISCHARGE (ESD)

The "-QP" products represented in this datasheet are regulated under the International Traffic in Arms Regulations (ITAR)
Public Domain Information – Previously Approved for Public Release (DOD Office of Security Review, Case 08-S-0596)

Absolute Maximum Ratings

Supply Voltages

Between GNDs -0.3V to +0.3V
Between VCCs -0.3V to +0.3V
VCCs to GND 0V to +3.8V

RF Input Voltages

CLKIP, CLKIN to GND -3 V to 1 V

HS Digital Input Voltages

DI<0:11> 0V to VCC

Output Termination Voltages

OUTP, OUTN to GND -1 V to 1 V

Temperature

Case Temperature..... -40 to +85 °C
Junction Temperature..... +125 °C
Lead, Soldering (10 Seconds) +220 °C
Storage..... -60 to 125 °C

20.0	OPERATING TEMPERATURE² (note 2)						
20.1	Case Temperature	T _c	Measured at Bottom Plate	-40		85	°C
20.2	Junction Temperature	T _j				125	°C

¹ The DAC core current is generated from an internal reference that is both temperature and supply dependent. The Internal reference can change up to ±2% by changing the supply voltage within the specified range. It can also change up to ±5% according to operating temperature changes. The change in temperature and supply can be minimized by using a precision external voltage reference source connected to VREFA.

² The part is designed to function with a junction temperature up to 125°C. For the best performance, operation within the specified temperature range with a proper heatsink attached to the device is recommended. The heatsink should be attached to the bottom of the PCB, on a metal pad connect by thermal vias to the metal pad where the part is soldered.

Theory of Operation

For best dynamic and static performance, the DAC employs 6-bit segmentation. The 3.3V NMOS compatible 12-bit digital data inputs are latched by a master-slave flip-flop immediately after the input buffer to reduce the data skew. The four-channel data are combined together by the 48:12 MUX and latched again. The 6 MSB data bits are decoded into thermometer code by a two-stage decoding block, and the 6 LSB data bits are transported through the delay equalizer block. The digital data are synchronized again by a second master slave flip-flop to reduce the switching glitch. The decoded 6 MSB data drive 63 identical current switches, and the 6 LSB data drive 6 current switches. The output nodes from the LSB current switches are connected to the analog output through an R-2R ladder to generate the binary output.

The DAC output full-scale voltage follows the relationship $V_{FS} = 0.3xV_{REF}$. An internal reference circuit with approximately -10dB supply rejection is integrated on chip for application convenience. The reference pin is provided for monitoring and for bypass purposes. To band-limit the noise on the reference voltage, the reference pin should be bypassed to the GNDA node with capacitance > 100pF. The VREF pin can also be used to override the internal reference with an accurate,

temperature-compensated external voltage reference.

The timing diagram is shown in Figure 5. The 1.3GHz external clock (HCLK) is divided by 2 and 4 resulting in the MUX internal selection signals S0 and S1. A low-speed clock (LCLK) is provided to drive the external digital. The four-channel data input are latched with an internal clock that is synchronized with the LCLK. Controlled by S0 and S1, input data are fed to the 1.3GS/s DAC in the order shown.

For applications requiring two MUXDACs, such as quadrature modulation, the RDA012M4MS offers master and slave mode operation. This provides synchronization between the two MUXDACs in a straightforward manner. Figure 7 illustrates two MUXDACs in an I-Q configuration and 1 GS/s conversion rate. The I-MUXDAC is in master mode and the Q-MUXDAC is in slave mode. The master MUXDAC generates an LVDS compatible 250MHz clock signal that is input to the slave MUXDAC where it is used to synchronize the generation of the select signal for the input muxes. The slave device then feeds this clock to the FPGA clock driver. For proper synchronization, the delay associated with the LVDS clock signal from master to slave MUXDAC must not exceed one clock period of the high-speed clock.

Figure 5 - Input Timing Diagram.

Signal Description

HIGH SPEED INPUT CLOCK.

The RDA012M4MS high-speed clock input is differential and can be driven from typical ECL circuits. Also a differential sinusoidal clock can be used. The HCLKIP and HCLKIN inputs, are internally terminated with $50\ \Omega$ to VTT which should be connected to a well decoupled -2.0 volt supply. Since the MUXDAC's output phase noise is directly related to the input clock noise and jitter, a low-jitter clock source is ideal. The internal clock driver generates very little added jitter (~ 100 fs). A 500MHz MUXDAC output demands a white noise induced clock jitter of less than 250fs for a 10-bit equivalent, 62dB SNDR.

DATA INPUT.

The data inputs are 3.3V NMOS-compatible. The data is interleaved according to significant bit. For example, consecutive data pins will occur as A0, B0, C0, D0, A1, B1, etc.

OUTPUT CLOCK.

Output clock LCLKOP and LCLKON are supplied for the DSP/FPGA/ASIC in slave mode, or connected to another MUXDAC if in master mode. They are LVDS compliant and needs to be terminated with a $100\ \Omega$ resistor in front of the clock driver for the ASIC/DSP.

For application convenience, the data input's setup and hold time is specified with respect to the LCLKO. It should be noted that LCLKOP and LCLKON are driven by the MUXDAC and the waveforms of these signals are better defined at the receiver end; that is, near the ASIC/DSP chip that provides the input data for the MUXDAC. The system designer should consider the delay associated with the signal routing in the system's timing budget.

The setup and hold time of the LCLK to data transition are defined at the MUXDAC side. Data transitions of the data input have to occur during the "Valid Data Transition Window." The timing margin seen from the MUXDAC is $T_P - T_S$ where T_P is the LCLKO period and T_S is the setup time, assuming that the ASIC chip takes LCLKO as the clock input and its outputs are latched at the

falling edge of the clock. From the ASIC/DSP end, however, the timing margin is decreased by the amount equal to the sum of the data delay and clock delay between the two chips.

ANALOG OUTPUT.

The outputs DACOUTP and DACOUTN should both be connected though a $50\ \Omega$ resistor to ground. This will give a full-scale amplitude of 0.6 volt (both outputs must be terminated), 1.2 volt differentially. The output common mode can be changed by terminating the load resistors to a different voltage. The device is optimized to perform best when connected to a voltage between 0 and 1 volt, however. For reliable operation, the output termination voltage should not exceed 3 volts.

REFERENCE.

VREFA is provided for added control of the full-scale amplitude output. The internal reference circuit is designed to provide -2.0 volts, which can change up to $\pm 5\%$ as the supply voltage and/or operating temperature changes. If the user prefers accurate absolute full-scale, use an external voltage reference with low output impedance to override the internal reference. The output full-scale voltage follows the relationship $V_{FS} = 0.3 \times V_{REF}$. Note that the MUXDAC is optimized to have the best performance with a reference voltage of -2.0 volts. The output resistance of the reference node is $560\ \Omega \pm 10\%$. VREFD allows adjusting of the digital circuitry bias point for varying input voltage swings. In most cases, VREFD should be bypassed to GND.

Typical Operating Circuit
